1. Introduction

- Body size as a trait (read Smith, Smith & Lyons) and over time why is it interesting? is there an optimal body size for every organism? how can it be determined? (-> stasis??)
- evolutionary models (read Gene Hunt's paper and Posada, 2003) -> make sense of evolutionary modes: * stasis * unbiased random walk * generalized random walk
 - body size in tortoises (why not use biomass? not necessary) distribution of tortoises (?)
- giant tortoises well suited for drifting on ocean currents (Meylan, 2000)
 - OR mammal megafauna extinctions -> giant tortoises
 - human and climatic influence
- purpose of this work: determine body size trends in tortoises and identify evolutionary mode (if possible). what lead to extinction?

2. Material & Methods

2.1. Data collection

I collected data on body size of fossil testudinids from the Miocene until recent times. The body size data set includes 26 fossil genera, comprising over 100 fossil species. The majority of the data was obtained from the primary literature (Table 23). To find relevant publications, I relied mostly on the references listed in the FosFarBase (Böhme and Ilg, 2003), the Paleobiology Database ((http://paleobiodb.org).), and the review by Rhodin et al. (2015). Furthermore, the FosFarBase provided fossil occurrences of testudinids all over the world, including their exact localities and age (Table ??, Fig. 1), which were used to get an overview over the availability of body size data. The FosFarBase (last accessed 23.03.2017) contained 769 testudinid occurrences between the Eocene (33.9 - 56 mya) and the Holocene from 647 localities (Fig. 1). Of those, 641 occurrences from 534 localities were of relevant age (Miocene to Holocene). The final body size data set, however, includes 376 data records from 193 localities, of which 106 localities are present in the FosFarBase.

put table only on CD?

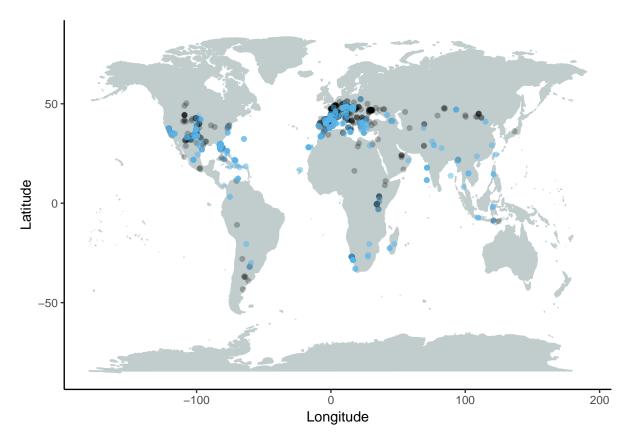

Figure 1: Map displaying all fossil occurrences of testudinids from the Eocene to the Holocene as according to the FosFarBase, with color indicating whether body size data was available (blue) or not (black).

For extant taxa, I measured dry material (n = 67) from the collection of the Museum für Naturkunde zu Berlin (MFN). In addition, body size data (n = 173) from the literature was included (Table 24).

2.2. Body size estimation

Body size is reported as straight carapace length (SCL) in mm. Where SCL was not available from the primary literature, it was estimated (n = 254) either from plastron length (PL) or appendicular elements (Table 23). For carapace length estimations based on plastron length, the measurements from the MFN collection material were used to calculate the ratio between SCL and PL. Since the SC/PL ratio was similar for all species (SCL/PL between 0.95 - 1.47), a single general ratio (SCL/PL = 1.1) was calculated for all testudinids and hence used for the SCL estimations unless stated otherwise (Table 23). For estimations based on femora and humeri, the ratios based on data provided by Hutterer et al. (1998) and Franz et al. (2001), respectively, were used. A number of publications did not state measurements but instead provided scaled figures of the fossil remains, from which either SCL directly or PL, humeri, or femora lengths for estimating SCL could be measured.

2.3. Analyses

All subsequent analyses were performed with R 3.4.1 (R Core Team, 2017), including the packages dplyr (Wickham et al., 2017) to prepare the data for the analysis and ggplot2 (Wickham, 2009) to create figures. The R package vegan (Oksanen et al., 2017) was used to create individual-based (?) accumulation curves, which show the increase in individuals, species or genera per sampling unit and are therefore used to determine if sampling is sufficient or not in terms of covering diversity and richness (Thompson and Withers, 2003). Most commonly these accumulation curves are conducted on individual or species level, but they can also be applied on higher taxa like families and genera (Gotelli and Colwell, 2011, 2001). The accumulation curves also give information about species richness, relative abundance and diversity (Thompson and Withers, 2003). Since the data set relies on literature, references were used as a sampling unit (x-axis).sampling accumulation curves were created on species as well as genus level, since genera of fossil testudinids are relatively well resolved by now whereas determination on the species level is still somewhat obscure in some cases, because fossil species are

add at some point that phylogenetics were not considered because not enough data for fossil species -> or only in discussion? fullevidence analysis would be

frequently based on single individuals that are often fragmentary as well (Brattstrom, 1961) + Lapparent de Broin, 2001. Since genera were better sampled than species (Fig. 3, 16 (a) - (b)), all subsequent analysis were performed on the generic level. Additional sampling accumulation curves for the continents were created (Fig. 16 (c) - (i)), to check if subsequent analyses could be applied to these subgroups. SACs: tell us if sampling is sufficient (covers all species) and can be used to estimate species richness randomization smooths out

2.3.1. Data strucure and statistics

Histograms and boxplots of the entire data set and several subgroups (fossil vs. modern, insular vs. continental) were created to explore the structure of the data set. General parameters like mean, median, variance, and with the package moments (Komsta and Novomestky, 2015) skewness and kurtosis were calculated (Table 20). The Wilcoxon Rank Sum Test (unpaired data) was used to test for differences between two subgroups. To be able to compare different subgroups, a subsample (1000 repeats) of the respective larger subgroup was taken to compare equal sample sizes.

2.3.2. Body size trends over time

To investigate trends in body size over time, the R package paleoTS (Hunt, 2015) was used. Data were split into time bins according to stratigraphic stages (Table 1, Fig. 2), although the two stages of the Lower Miocene were considered as one time bin, because the last bin otherwise would have contained only 2 data records. To prevent sampling bias and because Sampling Accumulation Curves showed that the genus level was well sampled in contrast to species level, the mean SCL per genus was calculated before the timescale analysis. The paleoTS plots were created, wich display the mean trait over time and can be fitted to different evolutionary models: stasis, which, generalized random walk (GRW), which or unbiased random walk (URW), which..... . The Akaike Weight Criterion (AICc) indicates which model is best supported —> see Catalina's Paper and Hunt's papers

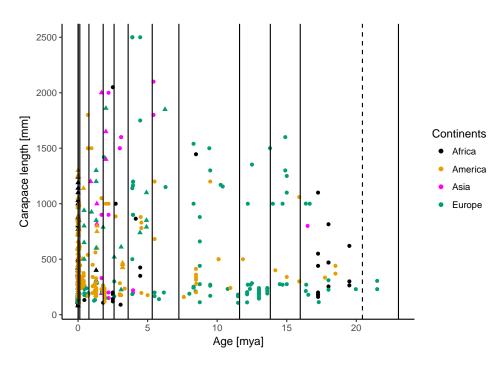

Figure 2: Scatterplot of carapace length over time, indicating insular (triangle) and continental (circles) and colour indicating continents. Lines indicate stratigraphic stages which were used as time bins, the dashed line is the border between the two stages of the Lower Miocene, which were consideres as one time bin.

Table 1: Time ranges, mean age per bin, corresponding stratigraphic stages and epochs, and respective sample sizes (on individual, species and genus level).)

3. Results

The sample-based accumulation curve on the generic level shows a relatively low intial slope and a long upward slope to the asymptote (does not reach asymptote in Fig. 3). In contrast, the species accumulation curves, both per reference and per locality show only a slight initial increase and, for the same number of references/sampling units, do not reach an asymptote (16 (a), (b)), as could be expected, since there are less genera than species cite Gotelli and Colwell, 2001. At a large geographic scale, it can be expected, that an asymptote is not reached cite Thompson et al., 2003. Fig. 3 corresponds to the shape one would expect, when there are many genera that are rare and only a few abundant ones. For the different continents, only Europe and Eurasia show some sort of "typical" SAC shape. Although the SAC does not completely plateau, considering the large area covered and the high number of rare genera in the dataset, it can be considered well enough sampled for our purposes. Since there are less genera than species in a taxon/clade (?), it is also to be expected, that genera reach an asymptote earlier than species. Accumulation curves for individual continents show that Europe reflects the trend of the overall dataet, with a long upward slope after the inflection point, whereas the other continents definitely require further sampling.

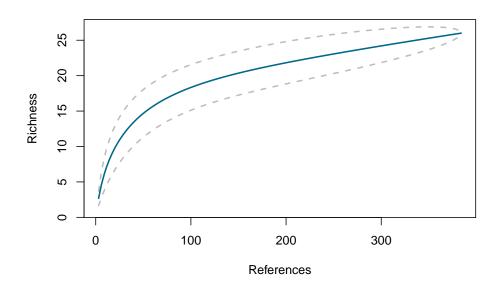

Figure 3: Sampling accumulation curve of fossil genera per reference. Dashed lines represent the confidence inteval.

read: Smith and Lyons, 2010 (?) and Smith et al., 2016 -> body size patterns (see also table

22, general statistics)

data is bimodal (not normally distributed -> fig.), still visible in pretty much all subgroups that you could split them into. as most animal groups/clades (?) right-skewed = smaller body size more frequent, BUT island species are left-skewed with more larger body sizes! (logtransformed data, skewness: negative for Zanclean, Messinian ??, insular, fossil-insular, but not modern-insular!!)

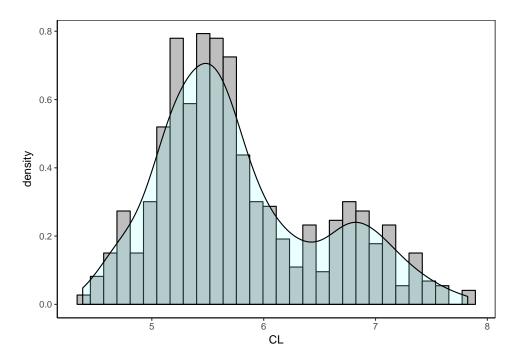

Figure 4: Body size distribution. Bimodally distributed.

need statistics for boxplot!! kruskal-wallis-test plus post-hoc test (+ bonferroni correction?) or moving mean (faysal?) you can kind of see how the median increases and then decreases again

(compare in order: Modern < Upper Pleistocene etc., do median and variance??)

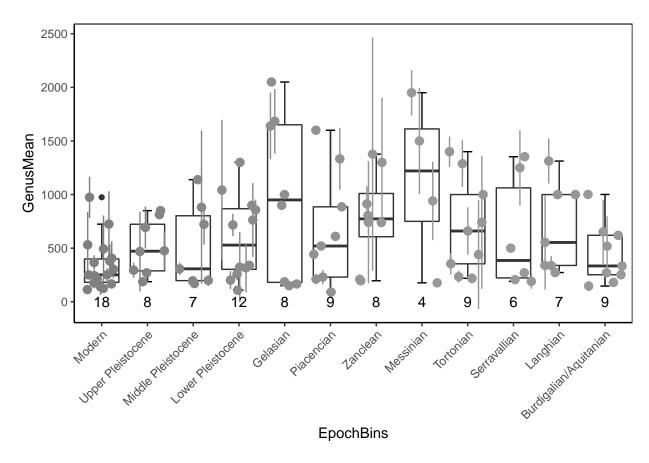

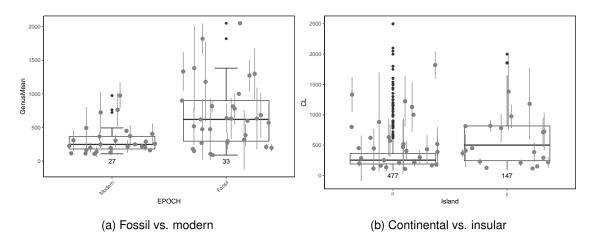

Figure 5: Boxplots of mean CL per time bin, including mean and sd CL for each genus (as pointrange).

modern tortoises are smaller than fossil ones and continental ones are smaller than insular ones (also true for modern-continental < fossil-continental and modern-insular < fossil-insular, right? think so...)

include modern-continental < modern-insular and fossil-continental < continental-insular? Wilcoxon Rank Sum Test (unpaired data):

modern < fossil (P = 2.6739885×10^{-7})

Wilcoxon Rank Sum Test (unpaired data): continental < insular (P = 1.5123×10^{-6})

4. paleoTS analysis

move paleoTS objects to appendix?

move Europe-continental-insular and Eurasia-continental-insular to Appendix! otherwise too much!

Appendix A Geographical and stratigraphic distribution of body size data

Body size data was available from all four continents, were testudinidae occur, and over a time period of 20 mya (Fig. 15, Table 1).

-> samples all over the world and over the whole time period with more or less equally distributed sample sizes (over time bins, continents are uneven -> see SAC)

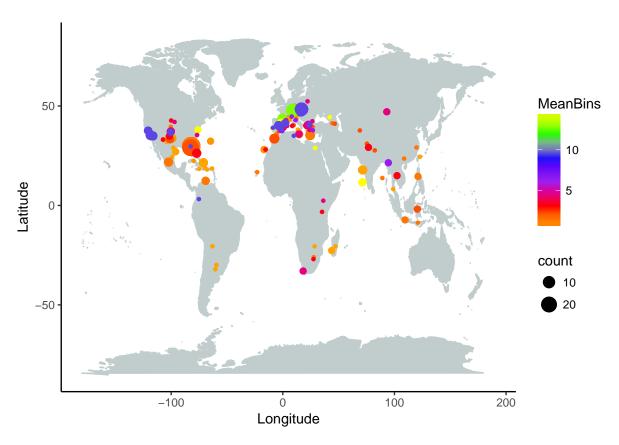

Figure 15: Map displaying all localities for which body size data for testudinids was available in the literature. Size of points denotes sample size, color denotes approximate age.

Appendix B Sampling accumulation curves

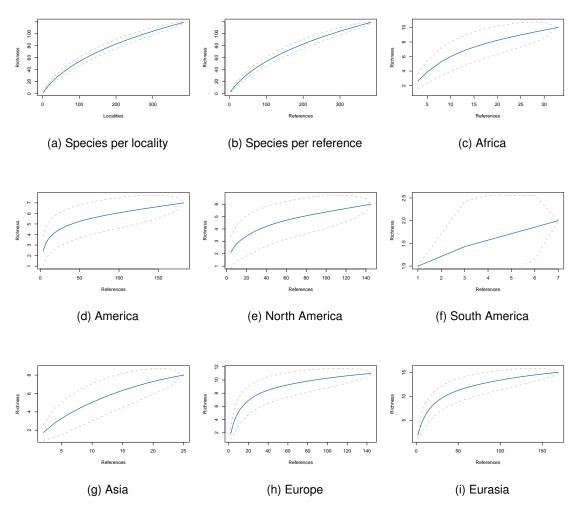

Figure 16: Sampling accumulation curves: (a) - (b) Species are not sufficiently sampled, regardless of sampling unit. (c) - (i) Sampling Accumulation Curves on generic level per continent. Only Europe (h) and Eurasia (i) are sufficiently sampled. Dashed lines represent the confidence interval.

Appendix C Histograms

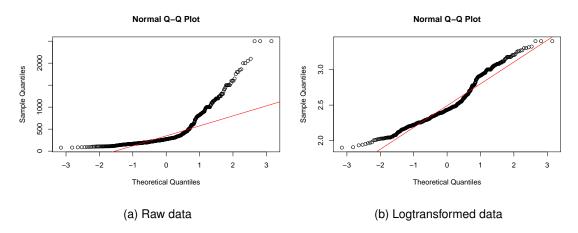

Figure 17: Visual test for normal distribution. In case of normally distributed data, the black circles should follow the red line, which is not the case for either raw data (a) nor logtransformed data (b). Therefore, data is not normally distributed.

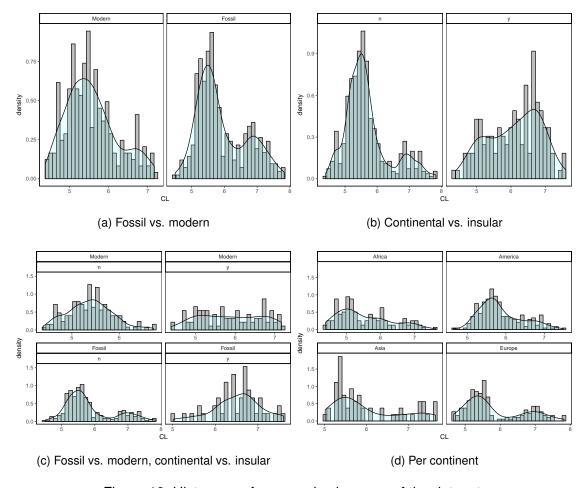

Figure 18: Histograms for several subgroups of the dataset.

Appendix D Boxplots

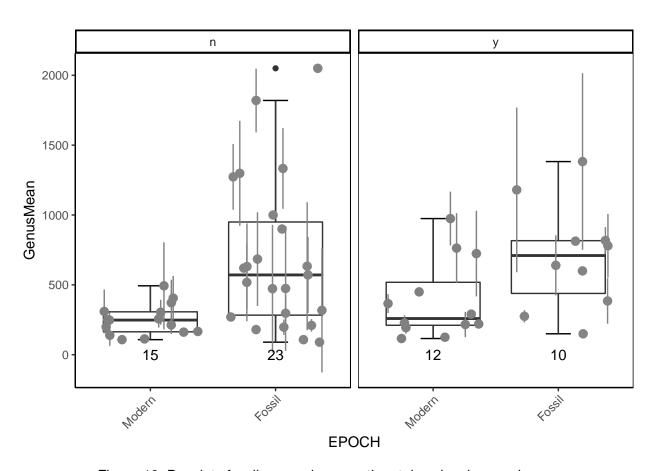

Figure 19: Boxplots fossil vs. modern, continental vs. insular species.

```
Wilcoxon Rank Sum Test (unpaired data):
```

modern continental < fossil continental (P = 4.8532266×10^{-8})

modern insular < fossil insular (P = 0.0018564)

Kruskal-Wallis-Test:

Continent means differ (P = 1.0833256×10^{-6}) (still have to look into the details. . .)

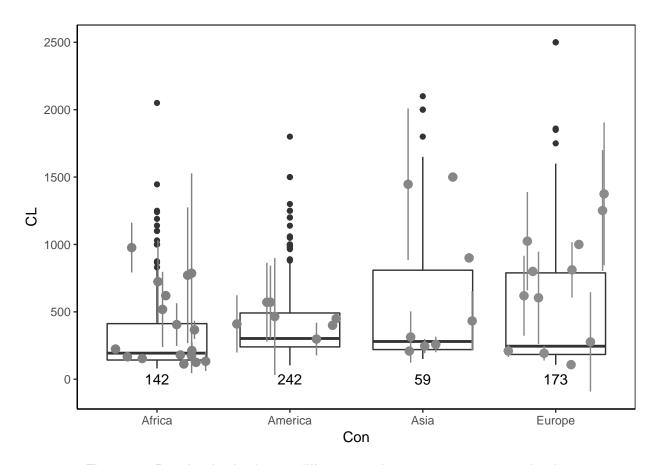

Figure 20: Boxplot: body size on different continents, genera summarised

Appendix E Random Sampling

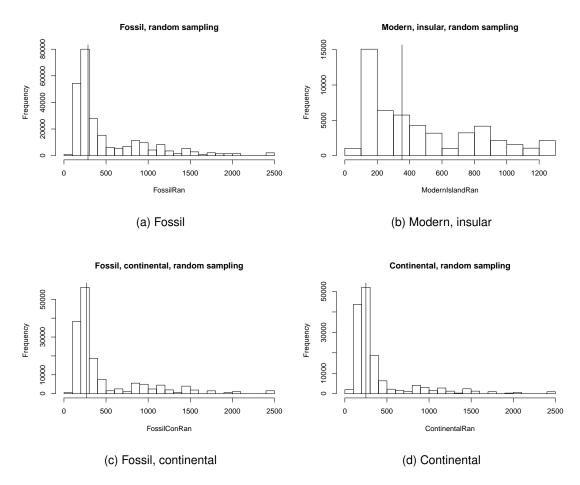

Figure 21: Random sampling for several subgroups. For (a), (c), and (d) the random sample reflects the real sample, for (b) this is not the case.

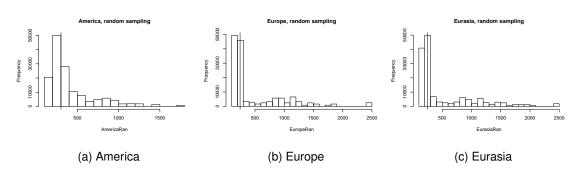

Figure 22: Random sampling for different continents. All random samples reflect the real sample.

Appendix F Tables

Table 20: General statistics of body size data: all, per time bin, insular and continental, per continent (all referring to CL: min, max, variance, mean, logmean, median, logmedian, skewness, logskewness, kurosis, logkurtosis
