1. Introduction

- Body size as a trait (read Smith, Smith & Lyons) and over time why is it interesting? is there an optimal body size for every organism? how can it be determined? (-> stasis??)
- evolutionary models (read Gene Hunt's paper and Posada, 2003) -> make sense of evolutionary modes: * stasis * unbiased random walk * generalized random walk
- body size in tortoises distribution of tortoises (?) giant tortoises well suited for drifting on ocean currents (Meylan, 2000)
 - OR mammal megafauna extinctions -> giant tortoises
 - human and climatic influence
- purpose of this work: determine body size trends in tortoises and identify evolutionary mode (if possible). what lead to extinction?

2. Material & Methods

2.1. Data collection

I collected data on body size of fossil testudinids from the Miocene until recent times. The body size data set includes 26 fossil genera, comprising over 100 fossil species. The majority of the data was obtained from the primary literature (Table S17). To find relevant publications, I relied mostly on the references listed in the FosFarBase (Böhme and Ilg, 2003), the Paleobiology Database (http://paleobiodb.org), and the review on fossil turtles and tortoises by Rhodin et al. (2015). Furthermore, the FosFarBase provided fossil occurrences of testudinids all over the world, including their exact localities and age (Table ??), which were used to get an overview over the availability of body size data. The FosFarBase (http://www.wahre-staerke.com/, last accessed 23.03.2017) contained 769 testudinid occurrences between the Eocene (33.9 - 56 mya) and the Holocene from 647 localities (Fig. 1). Of those, 641 occurrences from 534 localities were of relevant age (Miocene to Holocene). The final body size data set, however, includes 376 data records from 193 localities, of which 106 localities are present in the FosFarBase.

put table only on CD?

Figure 1: Map displaying all fossil occurrences of testudinids from the Eocene to the Holocene according to the FosFarBase, with color indicating whether body size data was available (blue) or not (black).

For extant testudinid taxa, I measured dry material (n = 67) from the collection of the Museum für Naturkunde zu Berlin (MFN) with an accuracy of the first decimal (unless stated otherwise) using calipers. In addition, body size data (n = 173) from the literature was included (Table S18).

2.2. Body size estimation

Body size is reported as straight carapace length (SCL) in mm. Where SCL for fossil taxa was not available from the primary literature, it was estimated (n = 254) either from plastron length (PL) or appendicular elements (Table S17). For carapace length estimations based on plastron length, the measurements from the MFN collection material were used to calculate the ratio between SCL and PL. Since the SC/PL ratio was similar for all species (SCL/PL between 0.95 - 1.47), a single general ratio (SCL/PL = 1.1) was calculated for all testudinids and hence used for the SCL estimations unless stated otherwise (Table S17). For estimations based on femora and humeri, ratios based on data provided by Hutterer et al. (1998) and Franz et al. (2001), respectively, were used. A number of publications did not state measurements but instead provided scaled figures of the fossil remains, from which either SCL directly or PL, humeri, or femora lengths for estimating SCL could be measured.

2.3. Analyses

All subsequent analyses were performed with R 3.4.1 (R Core Team, 2017), including the packages dplyr (Wickham et al., 2017) to prepare the data for the analysis and ggplot2 (Wickham, 2009) to create figures. The R package vegan (Oksanen et al., 2017) was used to create individual-based (?) accumulation curves , which show the increase in individuals, species or genera per sampling unit and are therefore used to determine if sampling is sufficient or not in terms of covering diversity and richness (Thompson and Withers, 2003). Most commonly these accumulation curves are conducted on individual or species level, but they can also be applied on higher taxa like families and genera (Gotelli and Colwell, 2011, 2001). The accumulation curves also give information about species richness, relative abundance and diversity (Thompson and Withers, 2003). Typically a species accumulation curve shows a steep initial slope followed by gradual plateuing until converging to an asymptote, when the maximum number of species has been reached. However, this shape can be affected in several ways, e. g. when a lot of rare species opposed to only a few abundant species are present or if

check correct term!

figure necessary?

sampling is conducted on a large geographical scale, the inflection point may be lower and the following slope towards the asymptote may be rather long or an asymptote may not be reached at all (Gotelli and Colwell, 2011, 2001). Since the data set in this study relies on literature, references were used as a sampling unit (x-axis). Sampling accumulation curves were created on species as well as genus level, since genera of fossil testudinids are relatively well resolved by now whereas determination on the species level is still obscure in some cases, because fossil species are frequently based on single individuals that are often fragmentary as well (Brattstrom, 1961; de Lapparent de Broin, 2001). Since genera were better sampled than species (Fig. 3, S2 (a) - (b)), all subsequent analysis were performed on the generic level. Additional sampling accumulation curves for the continents were created (Fig. S2 (c) - (i)), to check if subsequent analyses could be applied to these subgroups.

2.3.1. Descriptive statistics

Normalized histograms with density curves and boxplots of the entire data set and several subgroups (fossil vs. modern, insular vs. continental) were created to explore the structure of the data set. Descriptive statistics like mean, median, variance, and with the R package moments (Komsta and Novomestky, 2015) skewness and kurtosis were calculated (Table S14) for the raw data and log-transformed data. While mean, median and variance describe the location and distribution of a data set, skewness and kurtosis are referred to as 'shape statistics'. They give information about symmetry (skewness) and the weight of the tails compared to the rest of the distribution, i. e. outliers will results in a higher kurtosis. However, the accuracy and suitability of these shape statistics has been debated, since sample size, extreme values and homogeinity of the data impact their results and uncertainties are higher than mean, median and the like (McNeese, 2016; Bai and Ng, 2005). Especially for small sample sizes, the histograms should provide more appropriate information about the structure of the data set than skewness and kurtosis (McNeese, 2016).

The Wilcoxon Rank Sum Test (unpaired data) was used to test for differences in body size between modern and fossil taxa as well as between insular and continental taxa. To be able to compare different subgroups, a subsample (1000 repeats) of the respective larger subgroup was taken to compare equal sample sizes. The Kruskal-Wallis test was used to test for differences between more than two subsamples, e. g. body size per time bin and body size per continent. As post-hoc test, the Wilcoxon Rank Sum Test was used and a Bonferroni correction

SD

needed??

applied to adjust p-avlues.

2.3.2. Body size trends over time

To investigate trends in body size over time, the R package paleoTS (Hunt, 2015) was used. Data were split into time bins according to stratigraphic stages (Table 1, Fig. 2), although the two lower stages of the Miocene were considered as one time bin, because the last bin otherwise would have contained only 2 data records. To prevent sampling bias and because sampling accumulation curves showed that the genus level was better sampled than species level, the mean SCL per genus was calculated before the timescale analysis. The paleoTS plots display the mean trait over time and can be fitted to different evolutionary models: stasis, where the trait mean fluctuates around a steady mean (no change), generalized random walk (GRW), where changes in trait mean increases or decreases over time (directional change) or unbiased random walk (URW), where trait means change over time but not in a way where they accumulate and move in a specific direction (non-directional change). Model fits are based on maximum-likelihood estimation and model support is reported as Akaike Information Criterion (AICc), with the lowest values indication the best suited model. Additionally, Akaike weights are reported, which give the proportional support for each model. paleoTS plots and model-fitting was performed for the entire data set, continental and insular genera. The same approach was repeated for European and Eurasian genera for all data, as well as continental and insular genera separately.

> explain evolutionary models/fits and AICc etc.

Figure 2: Scatterplot of carapace length over time, indicating insular (triangle) and continental (circles) and colour indicating continents. Lines indicate stratigraphic stages which were used as time bins, the dashed line is the border between the two stages of the Lower Miocene, which were consideres as one time bin.

Table 1: Time ranges, mean age per bin, corresponding stratigraphic stages and epochs, and respective sample sizes (on individual, species and genus level).)

| Age Range [mya] Mean Age [mya] | Mean Age [mya] | Stages | Epochs | n (Individuals) n (Species) n (Genera) | n (Species) | n (Genera) |
|--------------------------------|----------------|------------------------|--------------------|----------------------------------------|-------------|------------|
| 0 - 0.0117 | 0.00585 | Modern | Modern | 254 | 99 | 48 |

| 11.6 - 13.8 | 12.71400 | Serravallian | Middle Miocene | 27 | ∞ | 9 |
| 13.8 - 16 | 14.89500 | Langhian | Middle Miocene | 18 | 4 | 6 |
| 16 - 23 | 19.50000 | Burdigalian/Aquitanian | Lower Miocene | 31 | 15 | 6 |

3. Results

3.1. Sampling accumulation curves

The sample-based accumulation curve (SAC) on the generic level shows a relatively low intial slope and a long upward slope to the asymptote (does not reach asymptote in Fig. 3). In contrast, the species accumulation curves, both per reference and per locality show only a slight initial increase and, for the same number of references/sampling units, do not reach an asymptote (Fig. S2 (a), (b)).

Although the SAC does not completely plateau, considering the large area covered and the high number of rare genera in the dataset, it can be considered well enough sampled for our purposes. Since there are less genera than species, it is also to be expected, that genera reach an asymptote earlier than species. Accumulation curves for individual continents show that Europe reflects the trend of the overall dataet, with a long upward slope after the inflection point, whereas the other continents definitely require further sampling.

Figure 3: Sampling accumulation curve of fossil genera per reference. Dashed lines represent the confidence inteval.

3.2. Descriptive statistics

The histograms indicate that testudinid body size is not normally distributed (Fig. 4), which is supported by QQ-Plots for raw as well as logtransformed data (Fig. S3). The body size

distribution is moderately right-skewed (Table S14), with a higher number of smaller body sizes. This pattern is also apparent when splitting the data set into fossil and modern time bins (Fig. S4 (a)). Considering insularity, body size distribution is right-skewed for continental taxa, but left-skewed for insular species, meaning larger bodys size occurs with a higher frequency than smaller body size on islands. Insular taxa are also left-skewed, when only considering fossil taxa, but modern insular taxa have a skewness close to 0, indicating a symmetric distribution. Kurtosis suggests light tails with no/few outliers (kurtosis < 3) for insular and modern insular species, whereas continental species have a heavy tail (kurtosis > 3). The histograms also show a bimodal distribution, with is also apparent on most sublevels, except for modern insular species. Body size distributions are similar, right-skewed and bimodal, for the four continents and reflect the overall trend (Fig. S4 (d)).

Figure 4: Body size distribution. Bimodally distributed.

Mean body size differs significantly across time bins (Kruskal Wallis Test, χ^2 = 71.441, P < 0.01; Fig. 5). Modern median body size is smaller than body size in the Upper Pleistocene (Wilcoxon Rank Sum Test, W = 3853.5, P < 0.01). There is no difference in body size within the Pleistocene (Wilcoxon Rank Sum Test, P > 0.05) and Pleistocene body size does not differ from body size in the Upper Miocene (Wilcoxon Rank Sum Test, P > 0.05). In the Middle Miocene, Serravallian body size is smaller than Langhian body size (Wilcoxon Rank Sum Test, W = 45, P

remove
time bins
from table descritpive
stats?!

 $< 0.01),\,but\,Langhian\,body\,size\,is\,not\,different\,from\,Lower\,Miocene\,body\,size\,(Wilcoxon\,Rank\,Rank)$

Sum Test, W = 311, P = 0.06).

Figure 5: Boxplots of mean CL per time bin, including mean and sd CL for each genus (as pointrange).

Figure 6: Boxplots of CL split into fossil vs. modern (a) and cotinental vs. insular (b)

Comparison of modern and fossil testudinids showed that modern tortoises were smaller than fossil ones (Wilcoxon Rank Sum Test, W = 22318, P < 0.01; Fig. 6). Furthermore, continental

mention random sam-pling?

check

vari-

ances?!

random

sampling

neces-

sary?

testudinids are smaller than insular taxa (Wilcoxon Rank Sum Test, W = 13854, P < 0.01; Fig. 6). These can even be considered in combination: modern continental taxa are smaller than fossil continental taxa (Wilcoxon Rank Sum Test, W = 8046, P < 0.01; Fig. S5) and modern insular taxa are smaller than fossil insular taxa (Wilcoxon Rank Sum Test, W = 631.5, P < 0.01; Fig. S5)) Finally, body size differs between continents (Kruskal Wallis Test, χ^2 = 34.343, P < 0.01; Fig. 5)

post hoc test!

4. paleoTS analysis

4.1. all (continental and insular)

Fitting of the three evolutionary models favoured stasis for the whole data set, although model support was not the best with only 51 % followed closely by 33 % support for unbiased random walk (Fig. 7, Table S1). When only considering continental genera, the best-fitting model was unbiased random walk, but again not ideally supported with 55 % (Fig. 8, Table 3). In contrast, insular genera are best described by stasis, which was very well supported (100 %; Fig. 9, Table 4)).

Figure 7: paleoTS plot with genus mean, all

| Stasis | -60.41581 | 2 | 127.2316 | 1 |

4.4. per continent

4.4.1. Europe, genera

When repeating the analysis for European taxa only, all three groups – all, continental and insular – are best described by stasis with model support between 92 - 99 % (Fig. 10, S9, S10; Tables 5, S6, S8).

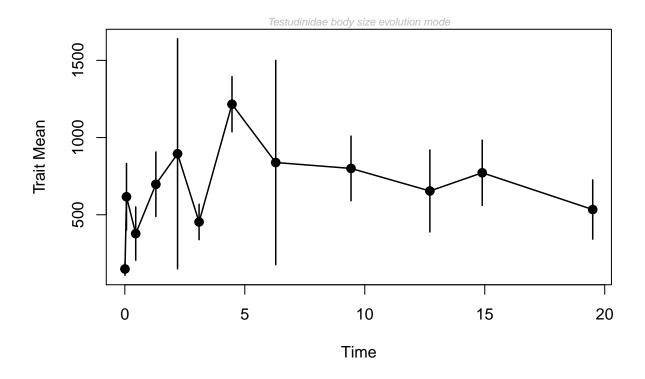

Figure 10: Genera, Europe

Table 5: Model-fitting results for testudinidae, genera, Europe

| | logL | K | AICc | Akaike.wt |
|--------|-----------|---|----------|-----------|
| GRW | -84.14010 | 2 | 173.7802 | 0.006 |
| URW | -85.90727 | 1 | 174.2590 | 0.005 |
| Stasis | -79.01365 | 2 | 163.5273 | 0.990 |

4.4.2. Eurasia, genera

For Eurasia, the entire data as well as continental genera are best described by an unbiased random walk, although model support weak again. Continental species still have a better support (78 %; Fig. S11, Table S11) than all Eurasian data with only 56 % (Fig. 11, Table ??). Insular Eurasian species, however, conform to stasis again, although with lower support values (68 %; Fig. S12, Table S13).

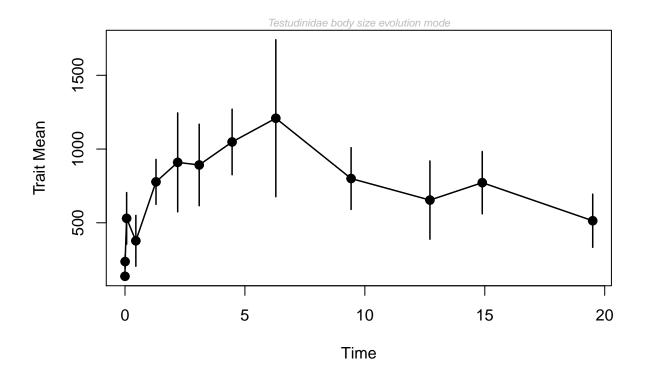

Figure 11: paleoTS, genera, Eurasia

| URW | -85.39072 | 1 | 173.1814 | 0.562 |
| Stasis | -84.58890 | 2 | 174.5111 | 0.289 |

5. Discussion

5.1. Completeness of data set

completeness of data set/benefits of additional sampling (SACs) - how much of the "actual" data is represented by our data set?

5.2. Population structure?

5.3. Time-scale analysis

-> what does model support depend on? what does a relatively low model support mean?

Appendix A Geographical and stratigraphic distribution of body size data

Body size data was available from all four continents, were testudinidae occur, and over a time period of 20 mya (Fig. S1, Table 1).

-> samples all over the world and over the whole time period with more or less equally distributed sample sizes (over time bins, continents are uneven -> see SAC)

Figure S1: Map displaying all localities for which body size data for testudinids was available in the literature. Size of points denotes sample size, color denotes approximate age.

Appendix B Sampling accumulation curves

Figure S2: Sampling accumulation curves: (a) - (b) Species are not sufficiently sampled, regardless of sampling unit. (c) - (i) Sampling Accumulation Curves on generic level per continent. Only Europe (h) and Eurasia (i) are sufficiently sampled. Dashed lines represent the confidence interval.

Appendix C Histograms

Figure S3: Visual test for normal distribution. In case of normally distributed data, the black circles should follow the red line, which is not the case for either raw data (a) nor logtransformed data (b). Therefore, data is not normally distributed.

Figure S4: Histograms for several subgroups of the dataset.

Appendix D Boxplots

Figure S5: Boxplots fossil vs. modern, continental vs. insular species.

```
Wilcoxon Rank Sum Test (unpaired data):
```

modern continental < fossil continental (P = 4.8532266×10^{-8})

modern insular < fossil insular (P = 0.0018564)

Kruskal-Wallis-Test:

Continent means differ (P = 1.0833256×10^{-6}) (still have to look into the details. . .)

Figure S6: Boxplot: body size on different continents, genera summarised

Appendix E Random Sampling

Figure S7: Random sampling for several subgroups. For (a), (c), and (d) the random sample reflects the real sample, for (b) this is not the case.

Figure S8: Random sampling for different continents. All random samples reflect the real sample.

Appendix F paleoTS

F.1 all (continental and insular)
